

Glossary terms from module 4

Terms and definitions from Course 2 Module 4

Application programming interface (API): A protocol that enables one application to interact with another application

Classification: The process of grouping items into a predefined category based on common characteristics

Clustered column: A user-defined table property that arranges storage blocks based on the values within their columns

Clustered table: A table in which column order is defined by the user, using clustered columns

Clustering: Grouping data points that are similar to each other in some way

Credentials: A username and password

Database partitioning: The process of dividing data into separate data segments or partitions that can be managed and accessed separately

Database schema: A way of describing how a database is organized

Dataproc: A fully managed service that maximizes open-source data tools for batch processing, querying, streaming, and machine learning

Functional partitioning: A process for dividing data into separate segments, in which data is grouped based on how it's used in different parts of the database system

Google Colab: A cloud-hosted version of Jupyter Notebook that allows users to write and execute Python in a browser, with no configuration required

Hadoop: A framework that distributes the processing of data across clusters of computers

Horizontal partitioning: A process for dividing data into separate segments, in which each partition or shard is its own data storage, but all shards follow the same organizational layout

Hyperparameters: Parameters whose value is used to control the learning process

Linear regression: A technique that estimates the linear relationship between a continuous dependent variable, and one or more independent variables

Machine learning: The use and development of algorithms and statistical models to teach computer systems to analyze and discover patterns in data

Partitioned table: A large table that is divided into smaller segments, or partitions, to improve query performance, and control costs by reducing the amount of data a query needs to process

Partition pruning: The process of eliminating unnecessary or irrelevant data from consideration when running a query

PySpark: A language for creating more automated analyses and pipelines

Ranking: The process of using characteristics to order items by likelihood

Software development kit (SDK): A set of software-building tools that includes groups of code libraries

SQL dialect: A version of SQL that is unique to a specific database

Syntax: The predetermined structure of a language that includes all required words, symbols, and punctuation, and their proper placement

Vertical partitioning: A process for dividing data into separate segments, in which each partition maintains a unique piece of the fields for items in the data store
